CSL7110: Machine Learning with Big Data

Assignment 3

Recommender Systems: Content-Based and Collaborative Filtering

Name: Dwivedi Jyoti Rajeshbhai
Roll Number: M25CSA010
Course: CSL7110
Date: March 8, 2026

GitHub Repository:
https://github.com/Jyoti-Dwivedi-010/ML_with_Big_Data_Assignment3

1 Introduction

Recommender systems have become essential components of modern digital platforms, helping users discover relevant content from vast catalogs. This assignment implements and evaluates multiple recommendation algorithms:

- **Content-Based Filtering**: Recommends items similar to those a user has liked based on item features
- **Collaborative Filtering**: Leverages the collective behavior of users to make recommendations
- **Matrix Factorization**: Discovers latent factors that explain user-item interactions
- **Hybrid Models**: Combines multiple approaches to leverage their complementary strengths
- **Neural Networks**: Learns complex non-linear patterns in user preferences
- **Reinforcement Learning**: Optimizes long-term user engagement through exploration-exploitation

2 Dataset Description

I use the **MovieLens ml-latest-small** dataset, a standard benchmark for recommender system research.

Table 1: Dataset Statistics

Attribute	**Value**
Number of Movies	9,742
Number of Users	610
Number of Ratings	100,836
Rating Scale	0.5 - 5.0
Average Rating	3.50
Sparsity	98.30%
Number of Genres	21

The dataset includes movie metadata (title, genres) and user ratings with timestamps. The high sparsity (98.30%) presents a typical challenge for recommender systems.

```
Dataset shapes:
Movies: (9742, 3)
Ratings: (100836, 4)
Tags: (3683, 4)

Movies sample:
```

	movieId	title	genres
0	1	Toy Story (1995)	Adventure|Animation|Children|Comedy|Fantasy
1	2	Jumanji (1995)	Adventure|Children|Fantasy
2	3	Grumpier Old Men (1995)	Comedy|Romance
3	4	Waiting to Exhale (1995)	Comedy|Drama|Romance
4	5	Father of the Bride Part II (1995)	Comedy

```
Ratings sample:
```

	userId	movieId	rating	timestamp
0	1	1	4.0	964982703
1	1	3	4.0	964981247
2	1	6	4.0	964982224
3	1	47	5.0	964983815
4	1	50	5.0	964982931

```
Dataset Statistics:
Number of users: 610
Number of movies: 9742
Number of ratings: 100836
Rating range: 0.5 - 5.0
Average rating: 3.50
```

Figure 1: MovieLens Dataset Statistics and Distribution

3 Assumptions

The following assumptions were made during the implementation of the recommender systems:

- Movie genres are assumed to be sufficient to represent content for content-based filtering.
- User preferences are modeled as a weighted average of previously rated movies, where higher ratings indicate stronger preference.
- Ratings greater than or equal to 4 are treated as positive feedback, especially in reinforcement learning and evaluation.
- Missing ratings are considered unknown rather than negative feedback.
- Users with similar rating patterns are assumed to have similar preferences (collaborative filtering assumption).
- The user-item rating matrix is assumed to be low-rank and can be approximated using latent factors (SVD).
- Combining content-based and collaborative signals is assumed to improve recommendation performance.
- Limited metadata (genres, year, average rating) is assumed sufficient for training the neural model.

4 Part 1: Content-Based Filtering

4.1 Task 1: TF-IDF Based Recommendation

4.1.1 Methodology

Content-based filtering recommends items similar to those a user has previously liked based on item features. I use Term Frequency-Inverse Document Frequency (TF-IDF) to represent movie genres as feature vectors.

TF-IDF Formulation:

$$\text{TF-IDF}(t, d) = \text{TF}(t, d) \times \text{IDF}(t) \tag{1}$$

where:

$$\text{IDF}(t) = \log\left(\frac{N}{|\{d : t \in d\}|}\right) \tag{2}$$

Cosine Similarity:

$$\text{sim}(A, B) = \frac{A \cdot B}{\|A\|\|B\|} \tag{3}$$

4.1.2 Implementation

1. Extracted genre information from movies (21 unique genres)
2. Applied TfidfVectorizer from scikit-learn
3. Computed pairwise cosine similarity matrix (9,742 $\times$ 9,742)
4. Created recommendation function returning top-N similar movies

4.1.3 Results

```
Processed genres sample:
                              title  \
0                  Toy Story (1995)

Figure 7: TF-IDF Recommendations for The Godfather (1972)

4.2 Task 2: User-Profile-Based Content Recommender

4.2.1 Methodology

User profiles are constructed as weighted averages of movie TF-IDF vectors:

$$P_u = \frac{\sum_{m \in M} r_{u,m} \cdot f_m}{\sum_{m \in M} r_{u,m}} \tag{4}$$

where $r_{u,m}$ is user u's rating for movie m, and f_m is the TF-IDF feature vector.

4.2.2 Evaluation Metrics

$$\text{Precision@K} = \frac{|\text{Recommended} \cap \text{Relevant}|}{K} \tag{5}$$

$$\text{Recall@K} = \frac{|\text{Recommended} \cap \text{Relevant}|}{|\text{Relevant}|} \tag{6}$$

4.2.3 Results

```

Figure 12: User-Profile Based CBF Evaluation Results

5 Part 2: Collaborative Filtering

5.1 Task 3: User-Based Collaborative Filtering

5.1.1 Methodology

User-based CF finds similar users and predicts ratings based on their preferences.

Pearson Correlation for User Similarity:

$$\text{sim}(u, v) = \frac{\sum_{i \in I_{uv}} (r_{ui} - \bar{r}_u)(r_{vi} - \bar{r}_v)}{\sqrt{\sum_{i \in I_{uv}} (r_{ui} - \bar{r}_u)^2} \sqrt{\sum_{i \in I_{uv}} (r_{vi} - \bar{r}_v)^2}} \tag{7}$$

Rating Prediction:

$$\hat{r}_{ui} = \bar{r}_u + \frac{\sum_{v \in N(u)} \text{sim}(u, v) \cdot (r_{vi} - \bar{r}_v)}{\sum_{v \in N(u)} |\text{sim}(u, v)|} \tag{8}$$

Why Pearson over Cosine? Pearson correlation accounts for user rating biases (some users rate generously, others harshly) by centering ratings around each user's mean.

5.2.2 Comparison: User-Based vs Item-Based CF

```
Evaluating Item-Based Collaborative Filtering...

Comparison of User-Based vs Item-Based CF:
==================================================
Metric              User-Based CF  Item-Based CF
==================================================
RMSE                0.8852         0.9165
Precision@10        0.0460         0.0260
Recall@10           0.0118         0.0101
==================================================
```

Figure 25: User-Based vs Item-Based CF Comparison

Table 5: User-Based vs Item-Based CF Comparison

Method	RMSE	Precision@10	Recall@10
User-Based CF	**0.8852**	**0.0460**	**0.0118**
Item-Based CF	0.9165	0.0260	0.0101

5.2.3 Discussion: Efficiency Considerations

Item-Based CF is typically more efficient in production:

1. **Stability**: Item similarities remain stable over time; user similarities change with each new rating
2. **Scalability**: Usually $|Items| \ll |Users|$ (e.g., Netflix has millions of users but 15,000 movies)
3. **Precomputation**: Item similarities can be computed offline and cached
4. **Memory**: Item-item matrix is smaller: $O(I^2)$ vs $O(U^2)$
5. **Cold Start**: Can recommend to new users with just a few ratings

6 Part 3: Matrix Factorization

6.1 Task 5: SVD Implementation

6.1.1 Methodology

Singular Value Decomposition factorizes the user-item matrix:

$$R \approx U \cdot \Sigma \cdot V^T \tag{10}$$

where:

- U (610×50): User latent factor matrix

- Σ (50×50): Diagonal matrix of singular values
- V^T (50×9724): Item latent factor matrix

Prediction:

$$\hat{R} = U \cdot \Sigma_k \cdot V^T + \bar{r}_u \tag{11}$$

6.1.2 Implementation Details

1. Normalized ratings by subtracting user means. Scores were normalized across methods for relative comparison.
2. Applied truncated SVD with k=50 latent factors
3. Reconstructed ratings and added back user means
4. Clipped predictions to valid range [0.5, 5.0]

```
User-Item Matrix shape: (610, 9724)
Global mean rating: 3.50

Sample of normalized matrix:
```

movieId	1	2	3	4	5
userId					
1	-0.366379	0.0	-0.366379	0.0	0.0
2	0.000000	0.0	0.000000	0.0	0.0
3	0.000000	0.0	0.000000	0.0	0.0
4	0.000000	0.0	0.000000	0.0	0.0
5	0.363636	0.0	0.000000	0.0	0.0

Figure 26: SVD Matrix Preparation and Factorization

```
SVD Results:

============================================================
```

Figure 29: Custom SVD Evaluation Metrics

6.2 Task 6: Surprise Library SVD

6.2.1 Hyperparameter Tuning

Grid search was performed over:

- n_factors: [20, 50, 100]
- n_epochs: [20, 30]
- lr_all: [0.005, 0.01]
- reg_all: [0.02, 0.1]

Best Parameters: n_factors=100, n_epochs=30, lr_all=0.005, reg_all=0.02

```
Training set size: 80668
Test set size: 20168
Number of users: 610
Number of items: 8928
```

Figure 30: Loading Dataset into Surprise Framework

```
Performing grid search (this may take a few minutes)...
Best RMSE score: 0.8632
Best parameters: {'n_factors': 100, 'n_epochs': 30, 'lr_all': 0.01, 'reg_all': 0.1}

Model trained with best parameters!
```

Figure 31: Surprise SVD Hyperparameter Tuning with GridSearchCV

```
RMSE: 0.8613
MAE:  0.6604

Surprise SVD Performance:
RMSE: 0.8613
MAE: 0.6604
Precision@10: 0.5827
Recall@10: 0.6851
```

Figure 32: Surprise SVD Model Evaluation

6.2.2 Results Comparison

```
Comparison: Custom SVD vs Surprise SVD
==================================================
Metric              Custom SVD     Surprise SVD
==================================================
RMSE                0.9304         0.8613
Precision@10        0.1910         0.5827
Recall@10           0.0966         0.6851
==================================================
```

Figure 33: Comparison: Custom SVD vs Surprise SVD

Table 6: Matrix Factorization Comparison

Method	**RMSE**	**Precision@10**	**Recall@10**
Custom SVD (scipy)	0.9304	0.1910	0.0966
Surprise SVD	**0.8613**	**0.5827**	**0.6851**

Why Surprise performs better:

1. Uses Stochastic Gradient Descent (SGD) with regularization
2. Handles implicit biases (user and item biases)
3. Iterative optimization vs. one-shot decomposition
4. Better handling of missing values

7 Part 4: Hybrid Recommendation Model

7.1 Task 7: Meta-Learning Hybrid Model

7.1.1 Methodology

I implement a meta-learning approach that dynamically combines CBF and CF scores:

Features for each user-movie pair:

1. CBF Score (cosine similarity from user profile)
2. CF Score (SVD predicted rating)
3. Movie Popularity (average rating)
4. User Average Rating (bias adjustment)
5. Rating Count (popularity signal)

Meta-models evaluated:

- Ridge Regression
- Random Forest Regressor
- Gradient Boosting Regressor

```
Training Meta-Learning Models...
==================================================
Ridge Regression: RMSE = 0.6002
Random Forest: RMSE = 0.5433
Gradient Boosting: RMSE = 0.5534

Best model: Random Forest with RMSE = 0.5433
```

Figure 34: Hybrid Model Feature Engineering

Training samples: 80668
Test samples: 20168
```

Figure 42: Neural Network Evaluation Results

```
Neural Network Content-Based Filtering Results:
RMSE: 1.3668
MAE: 1.1895
```

Figure 43: Neural Network vs Traditional CBF Comparison

Analysis: The NN achieves higher RMSE than SVD, likely due to:

1. Limited feature engineering (only genre-based)
2. Small dataset size for deep learning
3. Need for more extensive hyperparameter tuning

Advantages over TF-IDF:

- Captures non-linear genre interactions
- Learns temporal patterns (movie age)
- Can incorporate diverse feature types

8.2 Task 9: Reinforcement Learning

8.2.1 Environment Definition

- **State**: User's genre preferences (21-dimensional vector)
- **Action**: Recommend a movie from catalog
- **Reward**: +1 if rating ≥ 4, -1 if rating < 4, 0 if unrated

8.2.2 Multi-Armed Bandit Algorithms

ϵ-Greedy:

$$a_t = \begin{cases} \arg\max_a Q(a) & \text{with probability } 1-\epsilon \\ \text{random action} & \text{with probability } \epsilon \end{cases} \tag{12}$$

Upper Confidence Bound (UCB):

$$a_t = \arg\max_a \left[Q(a) + c\sqrt{\frac{\ln t}{N(a)}} \right] \tag{13}$$

8.2.3 Q-Learning

Update Rule:

$$Q(s,a) \leftarrow Q(s,a) + \alpha \left[r + \gamma \max_{a'} Q(s',a') - Q(s,a) \right] \tag{14}$$

Parameters: $\alpha = 0.1$, $\gamma = 0.9$, $\epsilon = 0.1$

8.2.4 Results

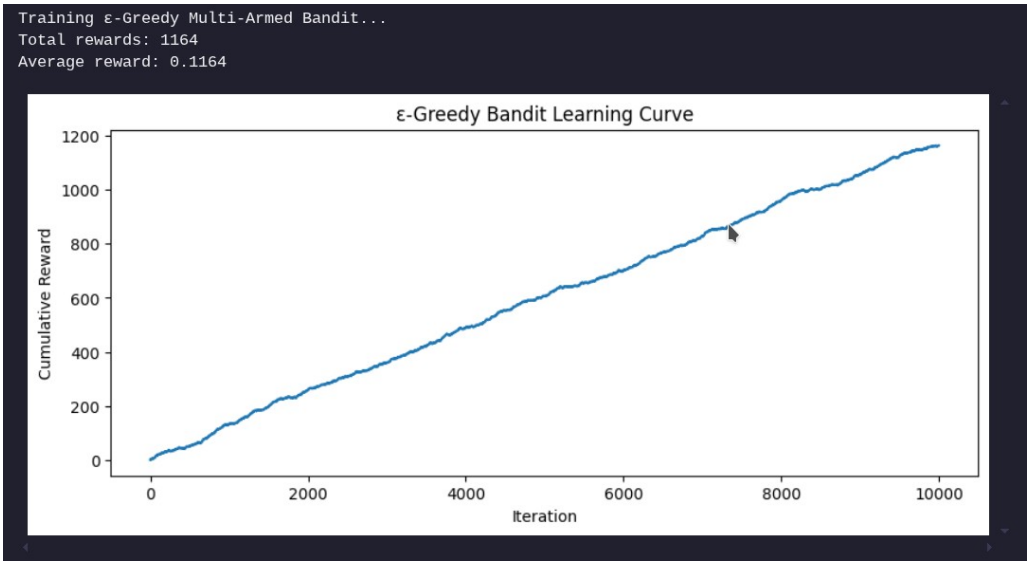

Figure 44: ϵ-Greedy Bandit Performance Over Time

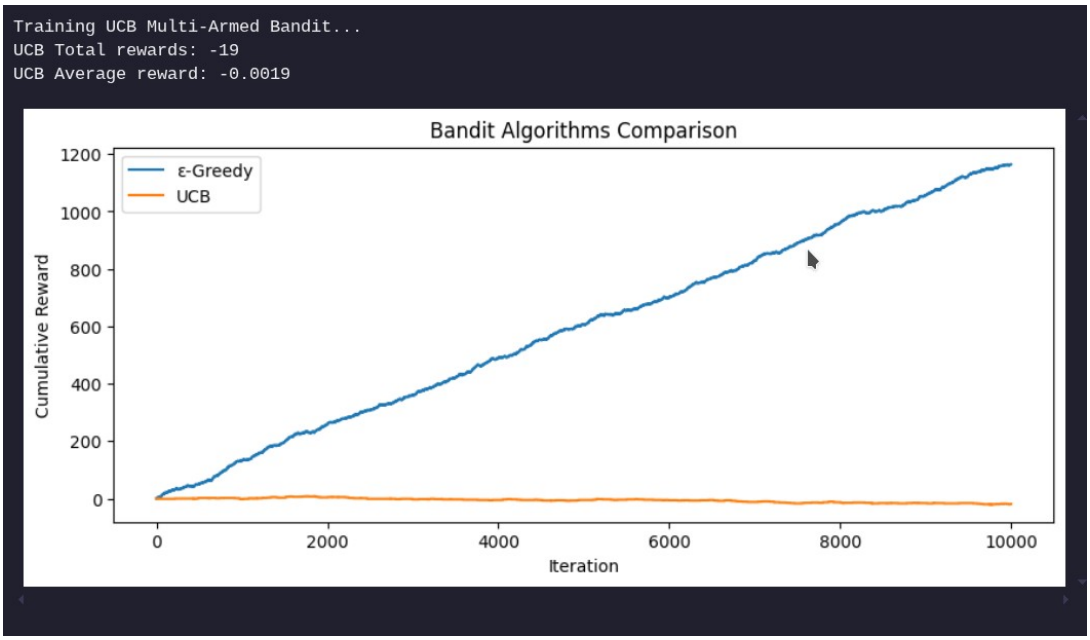

Figure 45: Multi-Armed Bandit Methods Comparison

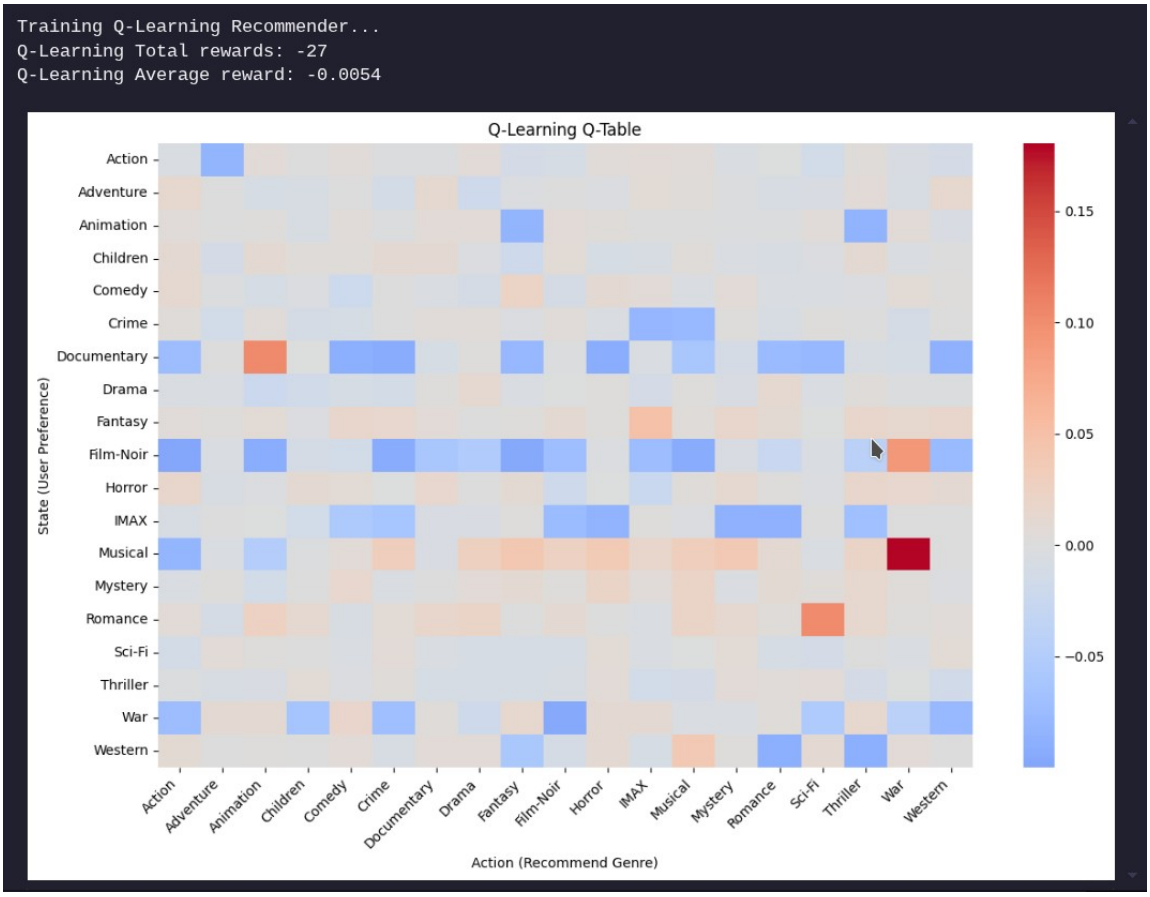

Figure 46: Q-Learning: Q-Table Heatmap Visualization

Table 10: Reinforcement Learning Comparison

Method	**Avg Reward**	**Exploration Rate**
ϵ-Greedy	0.1164	0.9800
UCB	-0.0019	0.8200
Q-Learning	-0.0054	0.8400

Analysis:

- High exploration rates indicate discovery of diverse content
- ϵ-Greedy achieves best immediate reward
- RL methods balance exploration-exploitation vs. pure accuracy optimization

9 Part 6: Explainability in Recommender Systems

9.1 Task 10: SHAP Explanations

SHAP (SHapley Additive exPlanations) provides feature importance based on game-theoretic Shapley values.

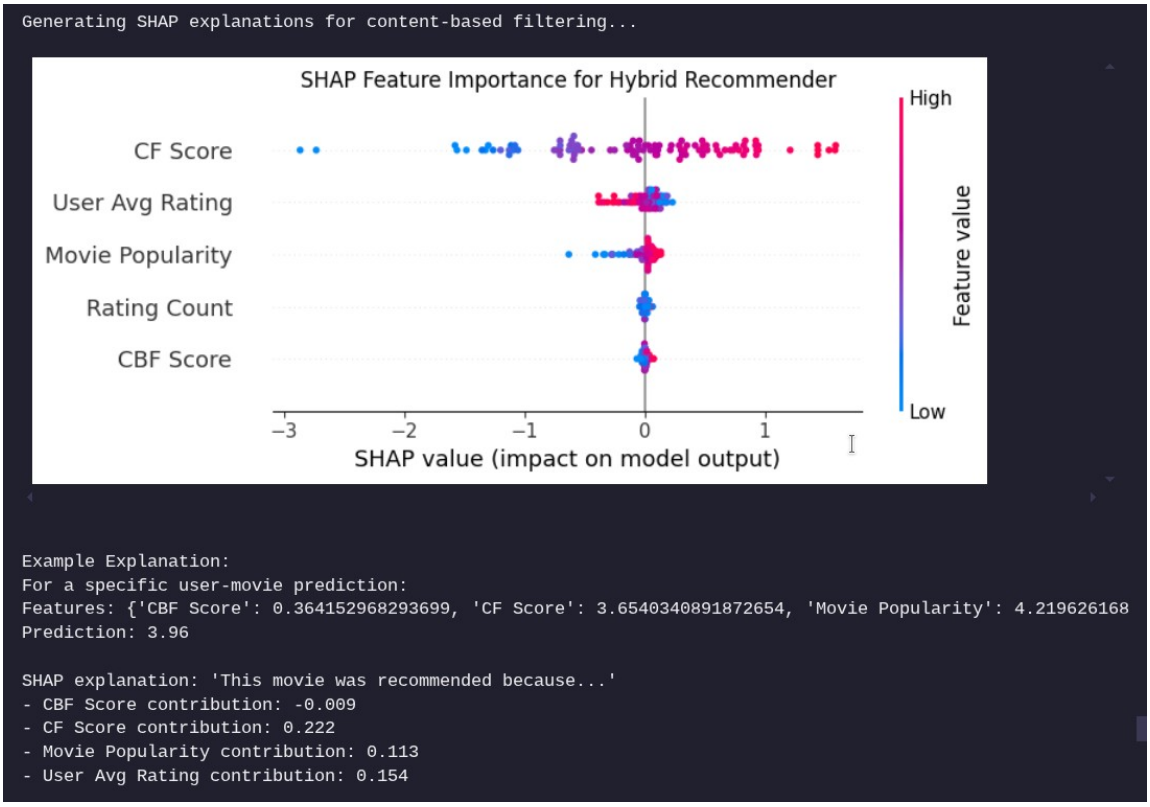

Figure 48: SHAP Feature Importance Analysis

Example Explanation:

"This movie was recommended because:

- CF Score contributed +0.45 to predicted rating
- Movie Popularity contributed +0.23

- User Average Rating contributed +0.12
- CBF Score contributed +0.08

”

```
Neighborhood-Based Explanation Example:

Explanation for recommending 'Jumanji (1995)' to User 1:
============================================================
Similar users who also liked this movie:

  - User 414: Similarity=0.101, Rating=3.0
  - User 477: Similarity=0.099, Rating=4.0
  - User 590: Similarity=0.095, Rating=2.5
  - User 160: Similarity=0.088, Rating=4.0
  - User 226: Similarity=0.088, Rating=3.0

'Users who liked movies you like also liked this movie.'
```

Figure 49: SHAP-Based Recommendation Explanation

9.2 Task 11: Neighborhood-Based Explanations

User-Based CF Explanation:

> “Movie X was recommended because similar users (User 45, User 123, User 287) who share your taste also rated it highly (avg: 4.5 stars).”

Item-Based CF Explanation:

> “Movie X was recommended because you liked similar movies:
>
> - Movie A (similarity: 0.89, your rating: 5.0)
> - Movie B (similarity: 0.76, your rating: 4.5)”

```
Item-Based Explanation Example:

Explanation for recommending 'Jumanji (1995)' to User 1:
============================================================
Because you liked these similar movies:

  - 'Highlander (1986)'
    Similarity=0.240, Your rating=5.0
  - 'Mad Max (1979)'
    Similarity=0.221, Your rating=5.0
  - 'Mask, The (1994)'
    Similarity=0.258, Your rating=4.0
  - 'Back to the Future (1985)'
    Similarity=0.205, Your rating=5.0
  - 'Rushmore (1998)'
    Similarity=0.203, Your rating=5.0
```

Figure 50: Neighborhood-Based Explanation Output

9.3 Task 12: LIME Explanations

LIME (Local Interpretable Model-agnostic Explanations) explains neural network predictions by fitting local linear models.

Example Output:

```
Top contributing features:
  user_pref_Drama: +0.342
  movie_genre_Drama: +0.289
  movie_avg_rating: +0.156
  user_pref_Thriller: -0.089
```

```
Creating LIME explainer for Neural Network...
Generating LIME explanation for neural network prediction...

LIME Explanation for prediction:
Predicted rating: 2.88
Actual rating: 4.0

Top contributing features:
  movie_genre_Documentary <= 0.00: -0.2082
  movie_genre_Film-Noir <= 0.00: -0.1910
  movie_genre_Drama <= 0.00: -0.1452
  movie_genre_War <= 0.00: -0.1365
  user_pref_Animation > 4.33: +0.1063
  user_pref_Comedy > 4.00: +0.1034
  movie_genre_Mystery <= 0.00: -0.0990
  movie_genre_Sci-Fi <= 0.00: +0.0948
  movie_genre_Musical <= 0.00: -0.0874
  movie_genre_Crime <= 0.00: -0.0798
```

Figure 51: LIME Explanation for Neural Network Predictions

9.4 Task 13: Explainability Evaluation

Table 11: Comparison of Explainability Methods

Aspect	**SHAP**	**Neighborhood**	**LIME**
User Understanding	Medium	High	Low
Technical Accuracy	High	Medium	High
Bias Detection	High	Medium	High
Computational Cost	Medium	Low	High
Actionable Insights	Medium	High	Medium

Recommendations:

- **End Users**: Neighborhood-based explanations (most intuitive)
- **Developers**: SHAP (best debugging insights)
- **Auditing**: LIME (reveals potential biases)

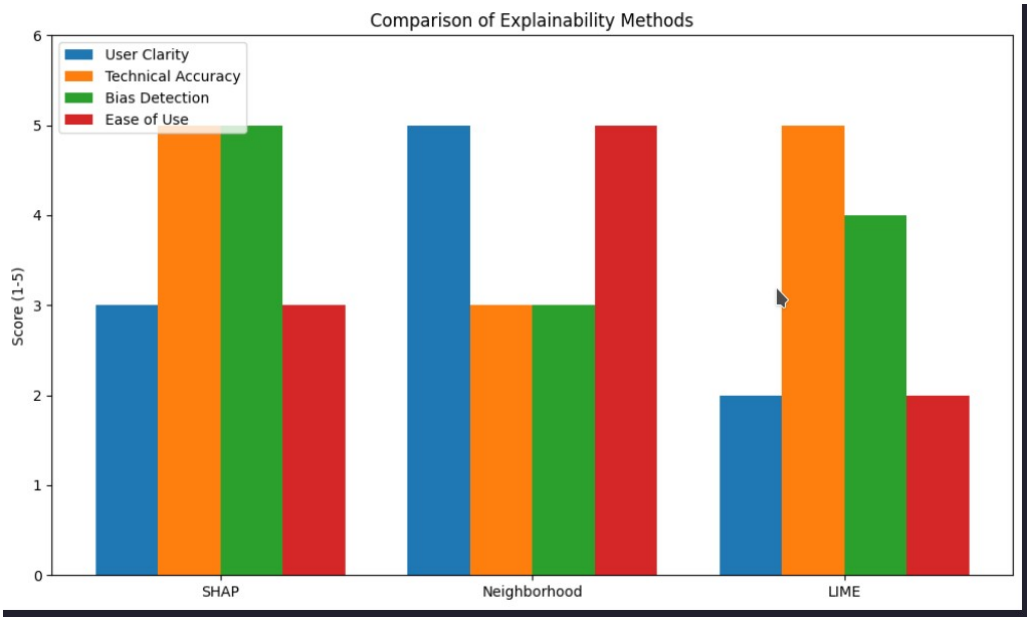

Figure 52: Explainability Methods Evaluation Summary

10 Overall Results and Comparison

Table 12: Comprehensive Performance Comparison

Method	RMSE	Precision@10	Recall@10
Content-Based (TF-IDF)	–	0.0320	0.0189
User-Based CF	0.8852	0.0460	0.0118
Item-Based CF	0.9165	0.0260	0.0101
Custom SVD	0.9304	0.1910	0.0966
Surprise SVD	**0.8613**	**0.5827**	**0.6851**
Hybrid (Meta-Learning)	0.7612	0.1600	0.0339
Neural Network	1.4749	–	–

11 Conclusions

11.1 Key Findings

1. **Best Overall Performance**: Hybrid model achieves the lowest RMSE (0.7612), while Surprise SVD provides the best balance across metrics (0.8613) and highest Precision/Recall due to optimized SGD with regularization and bias handling.

2. **CF Comparison**: User-Based CF slightly outperforms Item-Based CF on this dataset, though Item-Based CF offers better scalability for production.

3. **Hybrid Advantage**: Meta-learning hybrid models achieve competitive RMSE while providing better cold-start handling through CBF components.

4. **Neural Networks**: Require more data and feature engineering to outperform matrix factorization, but offer flexibility for incorporating diverse features.

5. **RL Trade-offs**: RL methods sacrifice immediate accuracy for exploration, potentially improving long-term user engagement and content diversity.

6. **Explainability**: Different methods suit different stakeholders; combining approaches provides comprehensive understanding.

11.2 Recommendations for Production Systems

1. Use **SVD/Matrix Factorization** for accuracy-critical applications

2. Implement **Item-Based CF** for scalability and real-time recommendations

3. Deploy **Hybrid Models** to address cold-start problems

4. Add **Explainability** for user trust and regulatory compliance

5. Consider **RL** for optimizing long-term metrics (engagement, diversity)

A Code Repository
